1 Default minted “C” lexer

```
def fn f(x) = x * sin(x * M_PI);
let vec3 position = vec3(0.0, 0.0, 0.0);
using namespace std;  POKE 59458,62;
xyzzy is a generic keyword;  removed stricken;
```

2 Custom lexer with new keywords

```
def fn f(x) = x * sin(x * M_PI);
let vec3 position = vec3(0.0, 0.0, 0.0);
using namespace std;  POKE 59458,62;
xyzzy is a generic keyword;  removed stricken;
```

3 Latex example

```

5 Custom keyword code

```
# pygments_custom
# This module uses environment variables to customize which
# keywords to highlight and which Pygments Lexer to inherit from.

from pygments.token import Name, Keyword
from pygments.lexers import *
from os import getenv
from sys import stderr
import json

# Previously we used "from pygments.lexers import CLexer as mysuper".
# Now, which lexer to inherit from is variable.
base = getenv( "PYGMENTS_CUSTOM_BASE_LEXER" )
if not base:
    base="CLexer"

try:
    mysuper = locals()[ base ]          # Do we have a class named that?
except KeyError:
    mysuper = CLexer
    print( f'\n*** CustomLexer Error: Unknown Lexer: "{base}". ',
           f'Defaulting to CLexer.', file=stderr )
    import pygments.lexers
    print( f'\n*** CustomLexer Error: Please set PYGMENTS_CUSTOM_BASE_LEXER '
           f'to one of {pygments.lexers.__all__}', file=stderr )

class CustomLexer(mysuper):
    """CustomLexer for pygments which extends an existing lexer with
    new keywords. The existing lexer defaults to CLexer but can be
    changed by the environment variable PYGMENTS_CUSTOM_BASE_LEXER.
    For example, one could inherit the C++ Lexer's keywords like so:

            export PYGMENTS_CUSTOM_BASE_LEXER="CppLexer"

    New keywords can be highlighted as Type, Constant, Namespace,
    Declaration, Pseudo, Removed, Reserved, or plain old Keyword. To
    add keywords, set the environment variables PYGMENTS_CUSTOM_TYPE,
    PYGMENTS_CUSTOM_CONSTANT, ..., PYGMENTS_CUSTOM_KEYWORD.

    Each variable is a Python list (square brackets surrounding a
    comma separated list of quoted strings). For example, this
    highlights new types (e.g., classes or typedefs):

            export PYGMENTS_CUSTOM_TYPE="[ 'vec3', 'Atom', 'System' ]"

    """
```

```
    name = 'Custom'
    aliases = ['custom']
    kwtable = [ ('PYGMENTS_CUSTOM_TYPE',        Keyword.Type),
                ('PYGMENTS_CUSTOM_CONSTANT',    Keyword.Constant),
                ('PYGMENTS_CUSTOM_NAMESPACE',   Keyword.Namespace),
                ('PYGMENTS_CUSTOM_DECLARATION', Keyword.Declaration),
                ('PYGMENTS_CUSTOM_PSEUDO',      Keyword.Pseudo),
                ('PYGMENTS_CUSTOM_REMOVED',     Keyword.Removed),
                ('PYGMENTS_CUSTOM_RESERVED',    Keyword.Reserved),
                ('PYGMENTS_CUSTOM_KEYWORD',     Keyword),               ]
    EXTRA = {}

    tr = str.maketrans( "'", '"' )         # transliterate python to JSON strings.
